Evidence-based guideline update: Steroids and antivirals for Bell palsy

ABSTRACT

Objective: To review evidence published since the 2001 American Academy of Neurology (AAN) practice parameter regarding the effectiveness, safety, and tolerability of steroids and antiviral agents for Bell palsy.

Methods: We searched Medline and the Cochrane Database of Controlled Clinical Trials for studies published since January 2000 that compared facial functional outcomes in patients with Bell palsy receiving steroids/antivirals with patients not receiving these medications. We graded each study (Class I–IV) using the AAN therapeutic classification of evidence scheme. We compared the proportion of patients recovering facial function in the treated group with the proportion of patients recovering facial function in the control group.

Results: Nine studies published since June 2000 on patients with Bell palsy receiving steroids/antiviral agents were identified. Two of these studies were rated Class I because of high methodologic quality.

Conclusions and Recommendations: For patients with new-onset Bell palsy, steroids are highly likely to be effective and should be offered to increase the probability of recovery of facial nerve function (2 Class I studies, Level A) (risk difference 12.8%–15%). For patients with new-onset Bell palsy, antiviral agents in combination with steroids do not increase the probability of facial functional recovery by >7%. Because of the possibility of a modest increase in recovery, patients might be offered antivirals (in addition to steroids) (Level C). Patients offered antivirals should be counseled that a benefit from antivirals has not been established, and, if there is a benefit, it is likely that it is modest at best. Neurology® 2012;79:2209–2213

GLOSSARY

AAN = American Academy of Neurology; AE = adverse event; CI = confidence interval; NNT = number needed to treat; RD = risk difference.

Bell palsy is an acute, peripheral facial paresis of unknown cause.1 Usually the diagnosis is established without difficulty.2 Up to 30% of patients with Bell palsy fail to recover facial function completely.3 The disease is common, with an annual incidence of 20 per 100,000. Thus, thousands of patients with Bell palsy are left with permanent, potentially disfiguring facial weakness each year.

In 2001, the Quality Standards Subcommittee of the American Academy of Neurology (AAN) published an evidence-based practice guideline for the treatment of Bell palsy.4 The 2001 guideline concluded that steroids were probably effective and antivirals (acyclovir) possibly effective in increasing the probability of complete facial functional recovery in patients with Bell palsy.

This update, developed by the AAN Guideline Development Subcommittee (see appendices e-1 and e-2 on the Neurology® Web site at www.neurology.org), systematically reviews studies published since June 2000 that are considered relevant to this question: For patients with new-onset Bell palsy, does treatment with steroids or antiviral agents (acyclovir, famciclovir, valacyclovir) improve facial functional recovery?
DESCRIPTION OF THE ANALYTIC PROCESS  
We searched Medline for articles published from June 2000 through January 2012 using the term “Bell’s palsy” and the sensitive, therapeutic clinical filter1 (see appendix e-3 for the specific search strategy employed). The Cochrane Database of Systematic Reviews and Controlled Clinical Trials was also searched. A secondary search of the references of selected articles and review articles (including Cochrane systematic reviews) was performed to identify studies missed by our search strategy.

The titles and abstracts of the identified citations were reviewed for relevance to the clinical question. The full text of potentially relevant articles was retrieved and included in the analysis if these studies determined facial functional outcomes after at least 3 months of follow-up in at least 20 patients with new-onset Bell palsy. We included only controlled trials with prospective data collection comparing outcomes in patients treated with steroids or antiviral agents with patients not treated with these medications. Both authors independently reviewed articles and completed data abstraction. Discrepancies were resolved through discussion.

Facial functional recovery was defined as “good” or “complete” using the same criteria used in the 2001 practice guideline. The quantitative measure of the treatment effect employed was the difference in the proportion of patients attaining complete or good facial recovery in the treatment group relative to the comparative group (i.e., the risk difference [RD]). In studies using the House and Brackmann facial function scoring system, we considered an outcome of grade I or II a good recovery. When comparing the proportion of patients recovering complete facial function, we considered an outcome of grade I a complete recovery. The measure of statistical precision used was the 95% confidence intervals (CIs) of the RD, and an RD ≥10% was considered clinically meaningful. The frequency and severity of the adverse events (AEs) from the treatments employed were also abstracted.

Studies were rated for their risk of bias using the AAN 4-tiered classification of evidence scheme for therapeutic studies (appendix e-4). Studies from the original guideline were re-rated using the updated classification of evidence scheme. The strength of practice recommendations was linked to the strength of evidence (appendix e-5).

For the purpose of formulating conclusions and recommendations, we used the term “steroids” regardless of the specific type, dose, and route of steroids used in the reviewed studies. Likewise, we used the term “antiviral agents” regardless of the specific type of agent used in the reviewed studies.

ANALYSIS OF EVIDENCE  
Our search strategy identified 340 citations. We reviewed the full text of 38 potentially relevant articles. Nine articles9–15 fulfilled the inclusion criteria.

For patients with new-onset Bell palsy, does treatment with steroids improve facial functional recovery? The search strategy identified 3 articles8,11,15 published since the initial review comparing outcomes in patients with Bell palsy treated with steroids with those not treated with steroids. Table 1 summarizes these studies and includes 2 of the studies reviewed in the original guideline that attained a grading of Class II or better.16,17 Only Class I and Class II studies are discussed further.

*aPercentage of patients with complete palsy.

*bMaximum duration of palsy before steroids started.

*cPercentage of subjects followed to study completion.

*dPercentage of patients not treated with steroids who attained a good outcome.

*ePrednisolone and prednisone are dose-equivalent steroids.

*fDowngraded by one Class from the rating in the original practice parameter because of no description of allocation concealment.
The 2 Class I studies\textsuperscript{4,13} randomized patients to steroids vs placebo and described concealed allocation. Both studies enrolled patients within 3 days of the onset of facial weakness. Both studies used prednisolone, one at 60 mg/d for 5 days followed by a 5-day taper,\textsuperscript{4} the other 25 mg BID for 10 days.\textsuperscript{13} All studies employed masked outcome assessment and had high rates of follow-up.

The 3 Class II studies\textsuperscript{5-17} did not describe concealed allocation. These studies enrolled fewer than 100 patients each and described complete follow-up and masked outcome assessment. One of the Class II\textsuperscript{5} studies used IV prednisone. The other 2 used oral steroid preparations.

**Efficacy.** The 2 Class I studies demonstrated a significant increase in the probability of complete recovery in patients randomized to steroids (RD favoring steroids 12.8% and 15%), translating to a number needed to treat (NNT) of 6 to 8. None of the Class II studies demonstrated a significant benefit from steroids. However, these studies lacked the statistical precision to exclude a clinically meaningful effect of steroids.

**Safety and tolerability.** All studies reported AEs from steroids. In general, these were minor and temporary. The most common AEs reported were insomnia and dyspepsia.

**Conclusion.** For patients with new-onset Bell palsy, it is highly likely that steroids are effective in increasing the probability of complete facial functional recovery (NNT 6–8, 2 Class I studies).

For patients with new-onset Bell palsy, does treatment with antiviral agents improve facial functional recovery? We found 8 articles\textsuperscript{7-14} published since 2000 comparing outcomes in patients with new-onset Bell palsy treated with antiviral agents. Five of these studies\textsuperscript{7,10,12-14} were rated Class IV because of nonindependent, nonmasked, nonobjective outcome assessment. These studies are not discussed further. Table 2 summarizes the remaining Class I and II studies (2 Class I, 1 Class II).\textsuperscript{8,10,11} The table also includes the single Class II study\textsuperscript{10} from the original guideline.

The Class I studies compared outcomes in patients randomized to antivirals and placebo. In addition, the Class I studies compared outcomes in patients on antivirals plus steroids with patients on steroids alone. The Class II studies\textsuperscript{10,18} compared outcomes only of patients on antivirals plus steroids with patients on steroids alone.

Valacyclovir was used in one study\textsuperscript{8} whereas acyclovir was the antiviral agent employed in the other studies. The doses are indicated in table 2. The majority of patients were enrolled within 3 days of onset of facial weakness.

**Efficacy.** None of the Class I studies demonstrated a significant improvement with the use of antivirals as compared with placebo (random-effects Mantel-Haenszel pooled RD 4% favoring placebo, 95% CI –3% to 11%). Although a benefit of antivirals was not observed in comparison with placebo, some authors have suggested antivirals might have an additional benefit when added to steroids.\textsuperscript{7}

All of the studies reviewed here specifically compared outcomes in patients on steroids and antivirals with patients on steroids alone (table 2). No significant benefit of antivirals added to steroids as compared with steroids alone was observed in the Class I and II studies. However, the 95% CIs of the Class I studies indicate that the studies’ statistical precision was insufficient to exclude a modest benefit or harm of antivirals added to steroids (random-effects Mantel-Haenszel pooled RD 0, 95% CI –8% favoring steroids alone to 7% favoring antivirals plus steroids). Adding the Class II studies to the meta-analysis fails to importantly increase the precision of the analysis (pooled RD 4% favoring steroids plus antivirals, 95% CI –4% to 12%).

**Safety and tolerability.** None of the studies demonstrated a significant increase in any AE for patients randomized to an antiviral agent.

Abbreviations: AC = acyclovir; CI = 95% confidence interval; HB = House Brackmann score; IQR = interquartile range; RD = risk difference (positive values results favoring antivirals); NH = natural history; VC = valacyclovir.

- **a**Percentage of patients with complete palsy.
- **b**Maximum duration of palsy before steroids started.
- **c**Percentage of subjects followed to study completion.
- **d**Percentage of patients treated with steroids only who attained a good outcome.
Conclusion. For patients with acute-onset Bell palsy, it is highly likely that antivirals do not moderately (RD > 7%) increase the likelihood of improved facial functional recovery (2 Class I studies). The pooled results of studies with a low risk of bias lack the statistical precision to exclude a modest benefit (RD favoring antivirals ≤7%) or modest harm (RD favoring steroids alone ≤8%).

RECOMMENDATIONS For patients with new-onset Bell palsy, oral steroids should be offered to increase the probability of recovery of facial nerve function (Level A).

For patients with new-onset Bell palsy, antivirals (in addition to steroids) might be offered to increase the probability of recovery of facial function (Level C). Patients offered antivirals should be counseled that a benefit from antivirals has not been established, and, if there is a benefit, it is likely that it is modest at best (RD <7%).

PUTTING THE EVIDENCE INTO A CLINICAL CONTEXT Although there is strong evidence that systemic antivirals do not increase the probability of recovery of facial nerve function (Level A), the risk of bias in these studies was high (2 Class I studies). The pooled results of studies with a low risk of bias lack the statistical precision to exclude a modest benefit (RD favoring steroids alone ≤8%).

RECOMMENDATIONS FOR FUTURE RESEARCH It is unlikely that additional research regarding the efficacy of steroids will change the current estimate of its effect. Large randomized trials comparing outcomes in patients treated with steroids receiving steroids with or without antivirals would help in determining whether the addition of antivirals to steroid treatment results in a modest benefit. Such trials should be powered to allow prespecified subgroup analyses of patients with a poorer prognosis and of patients with possible zoster sine herpete. Further future research efforts should be directed toward finding the optimal dose and timing of steroids, the effect of other therapeutic modalities, and the identification of the effect of steroids in specific populations, such as in children.

DISCLAIMER This statement is provided as an educational service of the American Academy of Neurology. It is based on an assessment of current scientific and clinical information. It is not intended to include all possible proper methods of care for a particular neurologic problem or all legitimate criteria for choosing to use a specific procedure. Neither is it intended to exclude any reasonable alternative methodologies. The AAN recognizes that specific patient care decisions are the purview of the patient and the physician caring for the patient, based on all of the circumstances involved. The clinical context section is made available in order to place the evidence-based practice recommendations into perspective with current practice habits and challenges. Formal practice recommendations are not intended to replace clinical judgment.

CONFLICT OF INTEREST The American Academy of Neurology is committed to producing independent, critical and truthful clinical practice guidelines (CPGs).
Significant efforts are made to minimize the potential for conflicts of interest to influence the recommendations of this CPG. To the extent possible, the AAN keeps separate those who have a financial stake in the success or failure of the products appraised in the CPGs and the developers of the guidelines. Conflict of interest forms were obtained from all authors and reviewed by an oversight committee prior to project initiation. AAN limits the participation of authors with substantial conflicts of interest. The AAN forbids commercial participation in, or funding of, guideline projects. Drafts of the guideline have been reviewed by at least 3 AAN committees, a network of neurologists, Neurology peer reviewers and representatives from related fields. The AAN Guideline Conflict of Interest Policy can be viewed at www.aan.com.
